	Perspectives

#### **Failure of classical genetics**

- 1. Gene effects explaining diseases are typically small (RR = 1.1-1.5) and not easily replicable
- Risky genetic variants often detected in only small subgroups of the population
   → do not explain a large proportion of diseases
- 3. Gene × environment show much stronger risks maintained over a long period
- 4. Genetic variants do not explain the heritability of common diseases ("missing heritability").
- 5. Changes in the genetic pool do not account for the temporal and spatial increases of diseases in the last 60 years.

lology
obesity

#### Genome:

 Building blocks for the manufacture of proteins needed for the cell functional activity (however, ~25,000 genes and ~2,000,000 proteins)

### **Epigenome:**

- Instruction on how, when, and where the information should be used
- Inheritance of variations above and beyond (epi) changes in the DNA sequence

Epigenetics  $\rightarrow$ 

Science studying heritable changes of genes that regulate gene expression, but do not involve changes in DNA sequence.

#### The five nucleotides that make up DNA

#### **Detection of DNA methylation**

Bisulfite conversion is the use of sodium bisulfite to convert cytosine residues to uracil, but leaving 5-methylcytosine residues unaffected.

→ Five nucleotides: - adenine, cytosine, uracil
 - guanine, thymine

# Exposures and epigenetics in the course of generations and the course of life

Accumulating evidence for the concept for *fetal programming:* 

Developmental conditions  $\rightarrow$  long-term consequences in childhood and adulthood

- Not the current complex settings of neighborhoods, air pollution, and food, but the (grand-)maternal conditions (fetal programming of offspring)
- Not all exposures during all periods of life, but in periods of change (e.g., gestation, puberty, menopause)

### So what went wrong with ma & grandma? How can we reverse it?

#### **GV** variants affect the methylation: methQTLs

• Genetic variants in adjacent areas impact the modality of the DNA methylation distribution.

#### **Exposure and methQTLs DNA-M**

• methQTLs interact with exposure to alter the DNA-M

Holloway, Karmaus, et al. manuscript in prep.

DNA methylation of *IL13* TSS1500 (cg04303330) as a result of *IL13* promoter rs1800925 and grown up on a farm (n=233)

# Changes in DNA methylation during mammalian development

# Associations between exposures and DNA methylation – large variety of exposures

- Diet (~650 articles)
- Smoking (~400 articles)
- Maternal stress and offspring DNA-M (~60 articles)
- PCB, DDE, persistent organic compounds (~60 publications, animals and humans)
- Air pollution (~30 articles)
- Maternal BMI (Hoyo et al. 2012, Gemma et al. 2009)
- Disadvantaged socio-economic position (SEP) in childhood (Borghol et al., 2011)

### Norwegian cohort (cord blood) and Isle of Wight birth cohort (blood at age 18)

Joubert et al. (2012) identified 26 methylated CpG sites in newborn cord blood samples that were potentially associated with maternal plasma cotinine (an objective biomarker of smoking) measured during pregnancy.

We found 38 CpG sites differentially methylated in girls at 18 years of age when the mother smoked during gestation.

Of 406,855 CpG sites tested, we found agreement between the two studies for 14 of 26 of the CpG sites identified in five of 10 genes.

Both studies identified

- AHRR

MYO1G

- CYP1A1 - *CNTNAP2* 

- -GFI1
- "Fingerprint" or a less specific "footprint" in the DNA-M profile?

6	<ul> <li>Ex: Gestational smoking &amp; childhood obesity</li> </ul>
7	Perspectives

#### **Different concepts for DNA-M as risk factors**

- 1. DNA methylation as independent variable
- 2. DNA methylation solely as intervening variable between exposure and disease (the magic bullet)
- DNA methylation, conditional on genetic variants, as intervening variable between exposure and disease

#### 1. The independent effect of DNA-M (T2DM)

Data provided by: Toperoff et al., Publication in: "Human Molecular Genetics, 2012, Vol. 21: 371–383 (peripheral white blood cells )

### 2. DNA methylation solely as intervening

#### **General findings**

- Genetic variants: relative risk between 1.1 to 1.5 (-3)
- DNA methylation: relative risk between 1.5 to 4

# Novel concept: What happens if we look at the interaction of genetic variants and methylation?

- 1. Karmaus et al., Curr Opin Allergy Clin Immunol 2013, 13:63–69
- 2. Soto-Ramírez et al. Clinical Epigenetics 2013, 5:1
- 3. Ziyab et al, Journal of the European Academy of Dermatology and Venereology a 2012

#### Large effects of DNA-M × modGV interactions

In all explored 13 genes, we found strong modifying effects of DNA-M on genetic variants (modGV)

Interaction between the IL4R gene (rs3024685: combined genotypes AA and AG vs. GG) and cg09791102 (pvalue adjusted for multiple testing =0.002) on the relative risk of asthma at age 18 (n=244, F1 women).

#### **Breakthrough in the relative risk**

Soto-Ramírez et al. Clinical Epigenetics 2013, 5:1

sample sizes

### **FLG** gene × DNA-M interaction for eczema

Interaction between the FI G gene (loss of function: R501X, 2282del, or S3247X) and methylation of cg07548383 on the risk ratio of eczema at age 18.

Ziyab et al, Journal of the European Academy of Dermatology and Venereology a 2012

#### **Genetic variants × DNA-M interaction**

- Genetic variants × DNA methylation

   → quantum leap in the estimation of relative risks:
   10-fold *plus* (for asthma, eczema, and allergy)
- A genetic polymorphism cannot have full penetrance if it is methylated. The strength of the modifying effect of DNA-M is stunning.

1	<ul> <li>Motivation to study epigenetic epidemiology</li> </ul>
2	Epigenetics
3	DNA methylation and exposures
4	DNA methylation and disease risks
5	Explanatory models
6	• Ex: Gestational smoking & childhood obesity
7	Perspectives

#### Mechanistic model using the promoter

#### **Mechanistic model – intragenic DNA methylation**

#### **Two-stage model**

#### Two-stage model:

- 1. Genetic variants in interaction with exposure change DNA methylation during developmental time windows.
- DNA methylation interacts with the genetic variants (masking or knockout genes – OR – strengthening their penetrance)
- Gene expression is altered OR different proteins will be produced.

2 • Epigenetics	
• DNA methylation and exposures	
ONA methylation and disease risks	
<ul> <li>• Explanatory models</li> </ul>	
• Ex: Gestational smoking & childhood obes	sity
Perspectives	

#### Example:

Gestational smoking and obesity in offspring (based on work by Mitra Yousefi)

- >90 studies: Maternal smoking → risk factor for offspring obesity
- In the US, at least 12 % of women continue smoking during pregnancy

→ >400,000 smoking exposed newborns

- US: >17 % of all children are obese, Worldwide: 150 million children – overweight 50 million - obese
- Is this epidemic inherited epigenetically?
- How can we reset it?

#### Gestational smoke exposure, BMI and leptin at age 18 in girls (n=235) 8

Leptin  $\rightarrow$  energy intake and energy expenditure

Body mass index 0 0  $\diamond$  $\diamond$ P=0.03 no yes

0

Maternal smoking during pregnancy

- Manufactured primarily in ۲ the adipocytes of white adipose tissue
- Binds to the leptin ٠ receptor which is encoded by LEPR gene

# How can gestational smoke exposure have a long-term effect on child's obesity?

- Investigate
  - genetic variants of the LEPR gene
  - DNA methylation of the LEPR gene

as step between gestational smoking and BMI in girls at 18

#### How do we find relevant information? Filtering: 1-2

 Focus on a limited number of SNPs: from 21 to 10

Linkage disequilibrium analysis of 14 *LEPR* SNPs and 7 *LEPROT* SNPs

#### Methylation at cg03050981

#### How do we find relevant information? Filtering: 3

**3**. Test at which CpG sites interact with affected by SNPs resulting in altered serum leptin levels:

16 CpG sites affected by methQTLs and gestational smoking  $\rightarrow$  2 interacted with modGV (SNPs)  $\rightarrow$  altered leptin levels

4. Corroborate whether the identified CpG × modGV interaction for serum leptin also affects BMI at age 18 years.

## Summary LEPR

- DNA methylation of LEPR is affected by maternal smoking and in turn may increase serum leptin levels and BMI.
- Limitation: other genes such as FTO
- Is this effect inherited epigenetically?
- If and how can we reset it?
- If we can reset the DNA-methylation, we may eliminate obesity not only in this but also in future generations.

# Central role of the environment (maternal and grand-maternal)

The biological game of life is adaptation to the conditions of existence (adapt or parish).

```
Environment

(evolution = slow)

Genome

(stable, inheritable)

Genetic disease→rare

Environment

(adaptation = quick)

Epigenome

(labile, inheritable)

Acquired disease→common
```

# Dream-come-true settings and new perspectives

- Depending on genetic variants, DNA methylation
   = archive of past exposures (finger- or footprint)
- 2. Genetic variants × DNA methylation  $\rightarrow$  diseases
  - ➔ DNA methylation links exposures with diseases
  - ➔ Quantum leap in the estimation of relative risks
  - ➔ 90-95% of the cases of asthma, eczema, allergy, and obesity can be explained

# Dream-come-true settings and new perspectives

3. Epigenetic research integrates

- Diverse dimensions of exposures
- Different scientific fields (cross-disciplinary)
- Social, psychosocial, chemical, and physical factors affect epigenetic marks
- 4. Birth cohort studies are essential to understand whether methylation and of which CpG is inherited, acquired during gestation, and is sustained to result in diseases in child- and adulthood.

Thank you

#### Questions

### **Target sequences for DNA methylation sites**

Begin: transcription start site (TSS)

Includes: regulatory sequences

End: 1 nucleotide before the start codon (usually AUG) of the coding region

#### Partial view of exon 3 – FLG gene
